(a) Distribution of charges

(b) Distribution of ions

Nernst equation

$$E = \frac{RT}{ZF} \ln \frac{[C]_{out}}{[C]_{in}}$$

R (Gas Constant) = 8.314472 (J/K·mol)

T (Absolute Temperature) = t °C +
273.15 (°K)

Z (Valence)

F (Faraday's Constant) = 9.6485309×10⁴
(C/mol)

[C]_{out} (Outside Concentration, mM)

[C]_{in} (Inside Concentration, mM)

E_{K^+}

$$E_{eq, K^+} = 61.54 mV \log \frac{[K^+]_o}{[K^+]_i}$$

$$E \text{ (mV)} = - 61. \log (C_i/C_o)$$

E = Equilibrium potential for a univalent ion

C_i = conc. inside the cell.

C_o = conc. outside the cell.

Goldman Hodgkin Katz equation

$$E_m = \frac{RT}{F} \ln \left(\frac{P_{Na^+} [Na^+]_o + P_{K^+} [K^+]_o + P_{Cl^-} [Cl^-]_i}{P_{Na^+} [Na^+]_i + P_{K^+} [K^+]_i + P_{Cl^-} [Cl^-]_o} \right)$$

i = Conc. inside

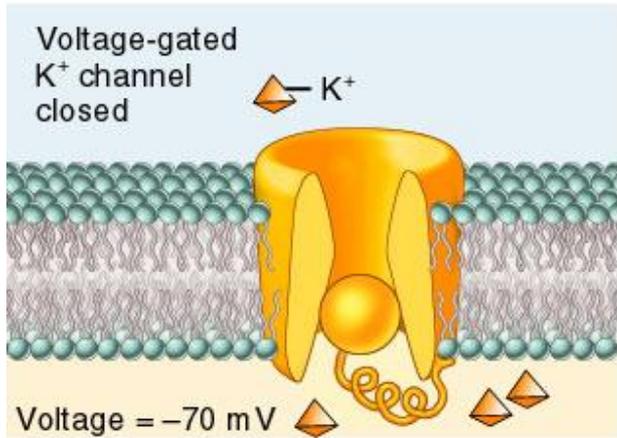

O = Conc. outside

P = permeability of the membrane to that ion.

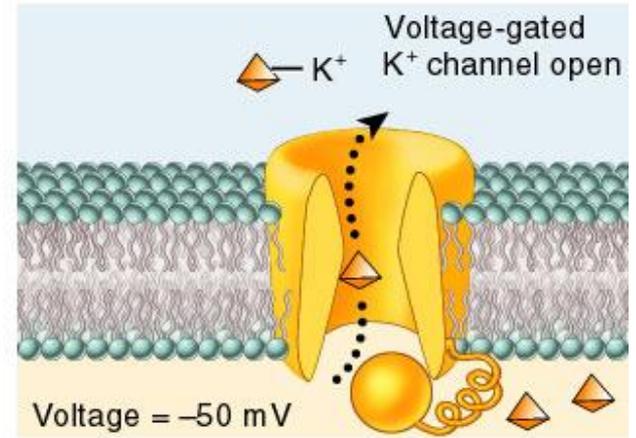

□ Extracellular fluid

■ Plasma membrane

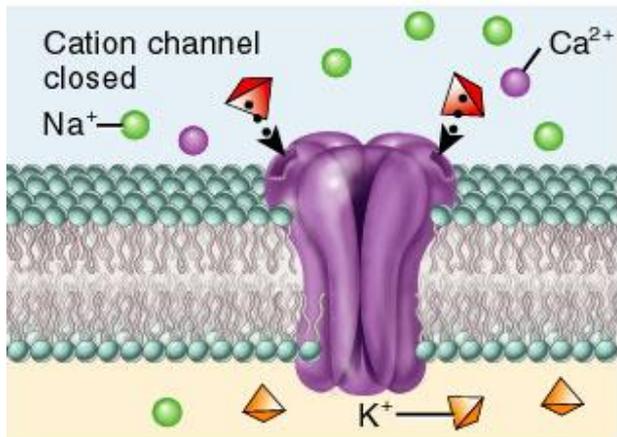

□ Cytosol

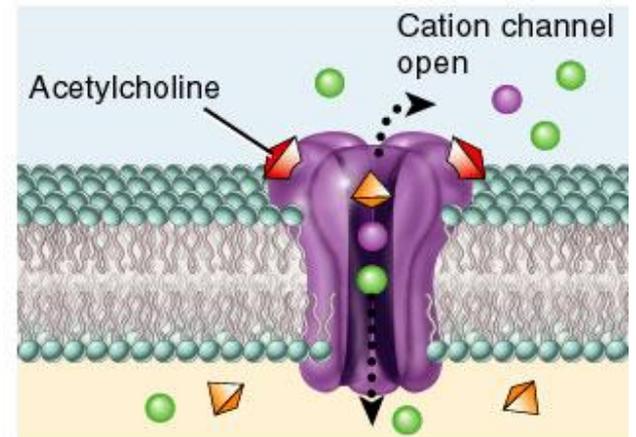

Change in membrane potential opens the channel

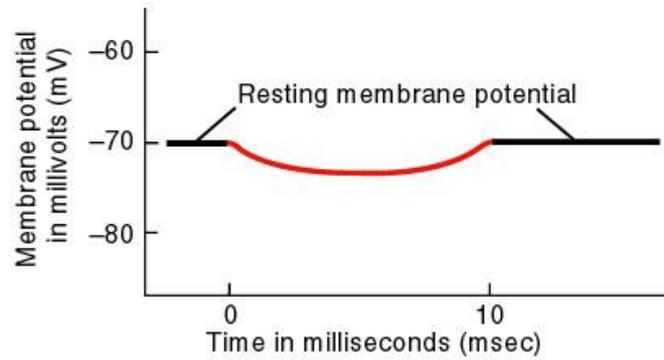

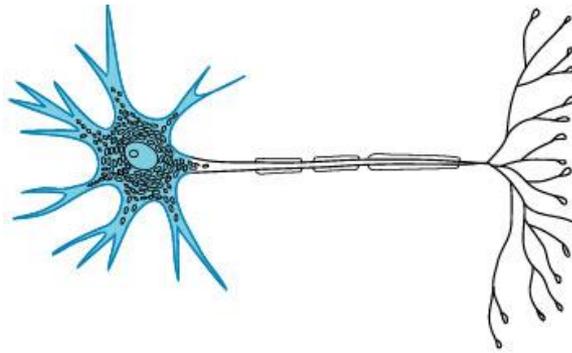

(a) Voltage-gated channel

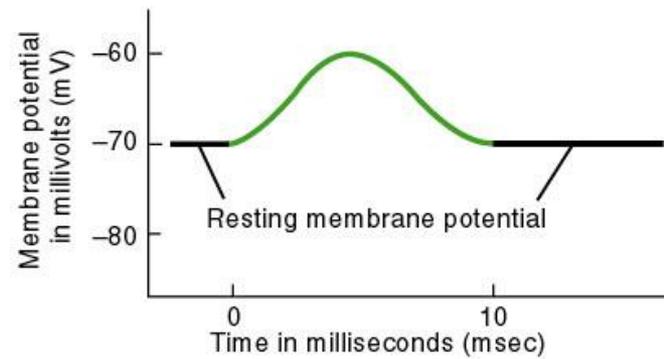

Chemical stimulus opens the channel

(b) Ligand-gated channel

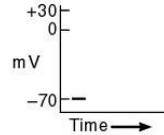

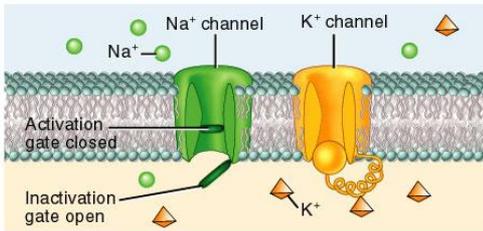

(a) Hyperpolarizing graded potential

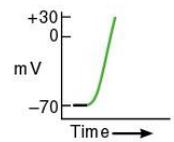

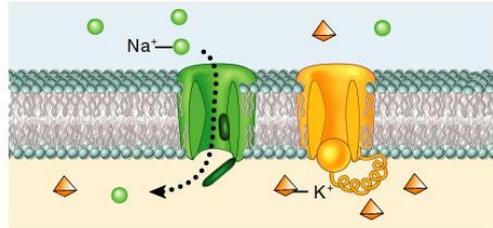

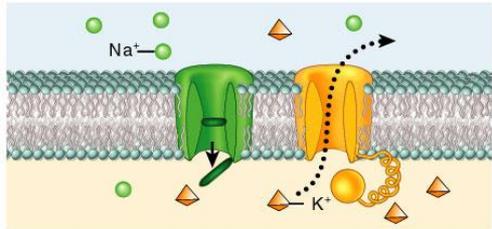

(b) Depolarizing graded potential

□ Extracellular fluid ■ Plasma membrane □ Cytosol

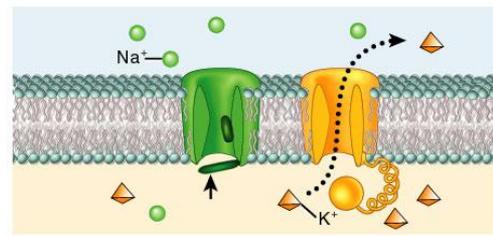

1. Resting state:
All voltage-gated Na⁺ and K⁺ channels are closed.

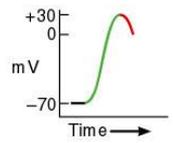

2. Depolarizing phase:
Depolarization to threshold opens Na⁺ channel activation gates. Na⁺ inflow further depolarizes the membrane, opening more Na⁺ channel activation gates.

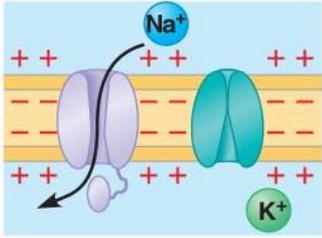

4. Repolarization continues:
K⁺ outflow restores resting membrane potential. Na⁺ channel inactivation gates open. Return to resting state when K⁺ gates close.

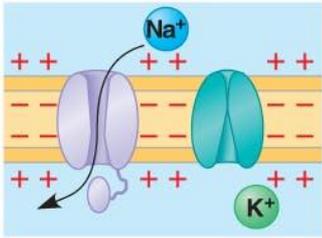

3. Repolarizing phase:
Na⁺ channel inactivation gates close and K⁺ channels open. Outflow of K⁺ causes repolarization.

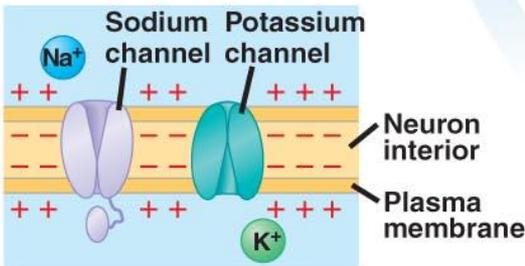

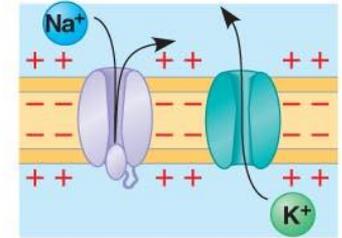

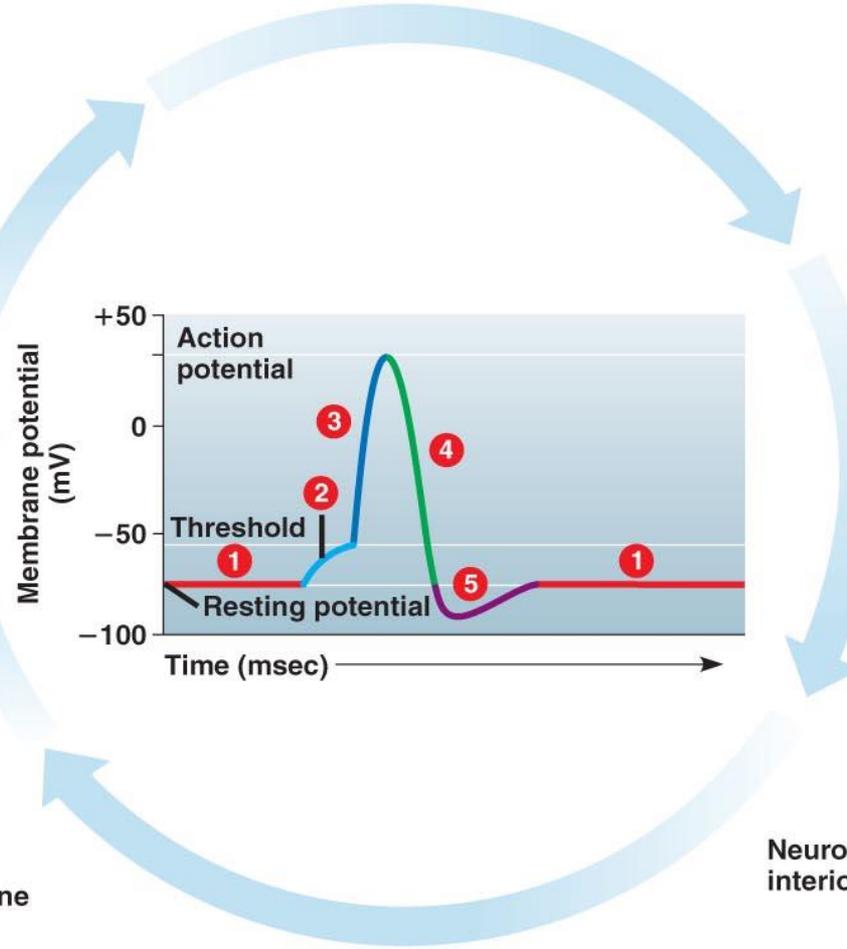

- 3** Additional Na^+ channels open, K^+ channels are closed; interior of cell becomes more positive.

- 2** A stimulus opens some Na^+ channels; if threshold is reached, action potential is triggered.

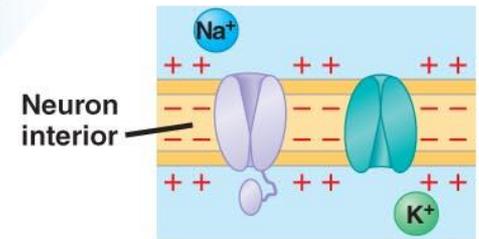

- 1** Resting state: voltage-gated Na^+ and K^+ channels closed; resting potential is maintained.

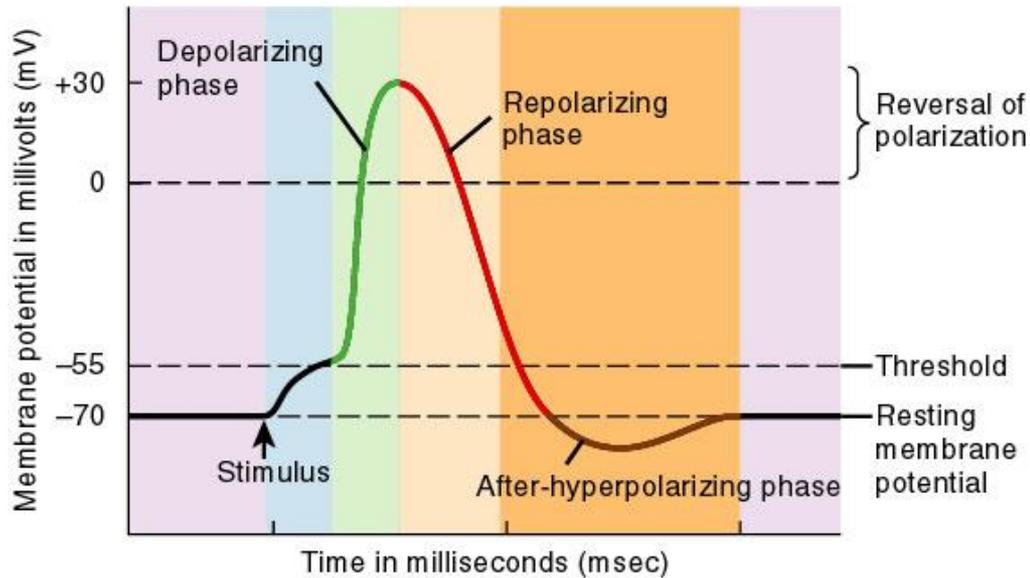

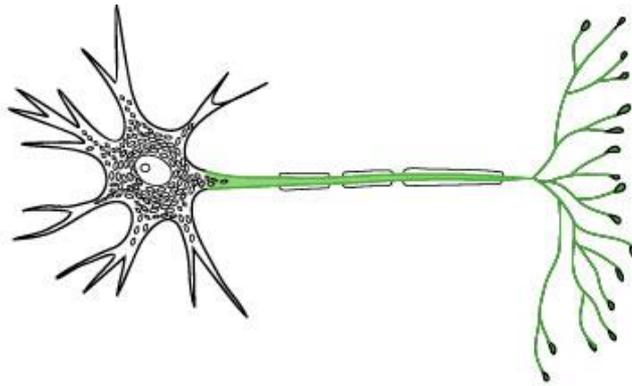

- 4** Na^+ channels close and inactivate. K^+ channels open, and K^+ rushes out; interior of cell more negative than outside.

- 5** The K^+ channels close relatively slowly, causing a brief undershoot.

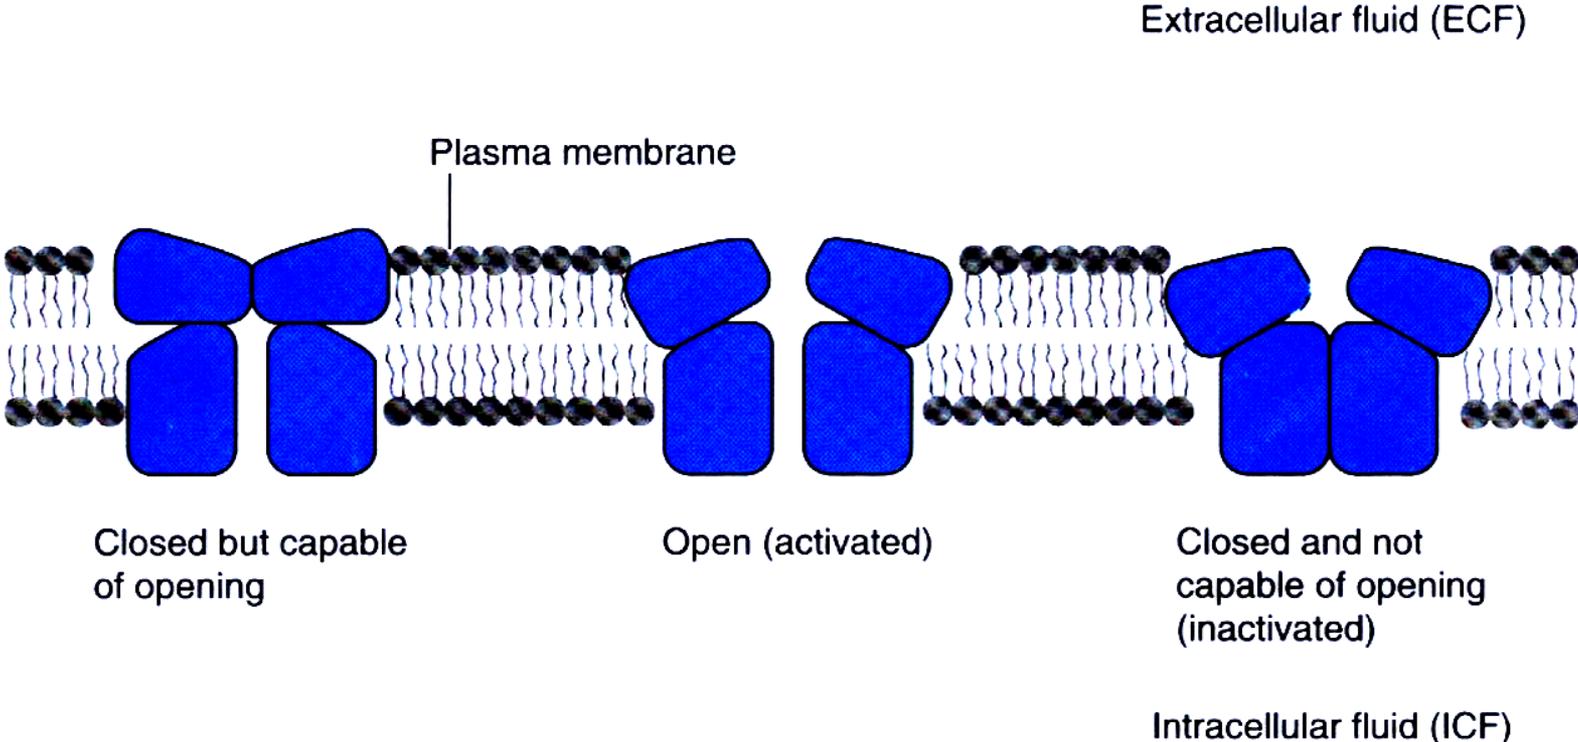

- 1** Return to resting state.

Key:

- Resting membrane potential: Voltage-gated Na^+ channels are in the resting state and voltage-gated K^+ channels are closed
 - Stimulus causes depolarization to threshold
 - Voltage-gated Na^+ channel activation gates are open
 - Voltage-gated K^+ channels are open; Na^+ channels are inactivating
 - Voltage-gated K^+ channels are still open; Na^+ channels are in the resting state
- } Absolute refractory period
- } Relative refractory period
